MAXMATCH - Maximum Self-Matching

no tags

You're given a string s consisting of letters 'a', 'b' and 'c'.

The matching function $m_s(i)$ is defined as the number of matching characters of s and its i -shift. In other words, $m_s(i)$ is the number of characters that are matched when you align the 0-th character of s with the i -th character of its copy.

You are asked to compute the maximum of $m_s(i)$ for all i ($1 \leq i \leq |s|$). To make it a bit harder, you should also output all the optimal i 's in increasing order.

Input

The first and only line of input contains the string s . $2 \leq |s| \leq 10^5$.

Output

The first line of output contains the maximal $m_s(i)$ over all i .

The second line of output contains all the i 's for which $m_s(i)$ reaches maximum.

Example

Input:
caccacaa

Output:
4
3

Explanation:

caccacaa
 caccacaa

The underlined characters indicate the ones that match when shift = 3.
